Shell structure, in building construction, a thin, curved plate structure shaped to transmit applied forces by compressive, tensile, and shear stresses that act in the plane of the surface. They are usually constructed of concrete reinforced with steel mesh ( see shotcrete ). Shell construction began in the 1920s; the shell emerged as a major long-span concrete structure after World War II.

A primary difference between a shell structure and a plate structure is that, in the unstressed state, the shell structure has curvature as opposed to the plates structure which is flat. Membrane action in a shell is primarily caused by in-plane forces (plane stress), but there may be secondary forces resulting from flexural deformations. Where a flat plate acts similar to a beam with bending and shear stresses, shells are analogous to a cable which resists loads through tensile stresses.

Introduction The concept of shell and core (or base build) is that the developer's scope of works is the design and construction of the base building. A range of other construction and fit out works are left to be completed before the building is occupied.
