It works by showing that if one randomly chooses objects from a specified class, the probability that the result is of the prescribed kind is strictly greater than zero.

The probabilistic method is a remarkable technique for proving the existence of combinatorial objects with specified properties. It is based on probability theory but, surprisingly, it can be used for proving theorems that have nothing to do with probability. The usual approach can be described as follows.

The Probabilistic Method

Emphasizing the methodology and techniques that enable problem-solving, The Probabilistic Method, Fourth Edition begins with a description of tools applied to probabilistic arguments, including basic techniques that use expectation and variance as well as the more advanced applications of martingales and correlation inequalities. The authors explore where probabilistic techniques have been applied successfully and also examine topical coverage such as discrepancy and random graphs, circuit ...

The basic Probabilistic Method can be described as follows: In order to prove the existence of a combinatorial structure with certain properties, we construct an appropriate probability space and show that a randomly chosen element in this space has the desired properties with positive probability. edges are the same color). The probability $A \cap R$ occurs for any given R is $2^{1-k} \binom{2}{k}$, since there are only 2 ways to color R , and thus the total probability that K_n is monochromatic is $2 \cdot 2^{-k} \binom{2}{k} = 2^{1-k} \binom{2}{k}$ and we can "union bound" this: the total probability is at most the sum of the probabilities of the independent events, so $\Pr(\text{monochromatic}) \leq \sum_{k=1}^n 2^{1-k} \binom{2}{k} = n \cdot 2^{-k}$

The Probabilistic Method in Combinatorics

The Probabilistic Method - Basic ideas We draw materials mainly from [2,4]. To show that some (combinatorial) object exists, one can envision working on some probability space which the object lives in, and show that the probability of such an existence is strictly positive.

The Probabilistic Method is one of the most powerful and widely used tools applied in combinatorics. One of the major reasons for its rapid development is the important role of randomness in theoretical computer science and in statistical physics.

The "probabilistic method" is the art of applying probabilistic thinking to non-probabilistic problems. Applications of the probabilistic method often feel like magic. Here is my favorite example: Theorem (Erdős, 1965). Call a set sum-free if for all $a, b \in S$, we have $a + b \notin S$. For any finite set of positive integers, there is a sum-free subset of size $\geq \frac{1}{3}|S|$.

This is exercise 2.7.2 of the book "the probabilistic method". Suppose $p > n > 10m^2$, with p prime, and let $0 < a_1 < a_2 < \dots < a_m < p$ be integers. Prove that there is an integer x , $0 < x < p$, for which the m numbers $(x + a_i) \pmod p$, $1 \leq i \leq m$ are pairwise distinct. And I think this problem in this way.

Definition: Probability sampling is defined as a sampling technique in which the researcher chooses samples from a larger population using a method based on the theory of probability. For a participant to be considered as a probability sample, he/she must be selected using a random selection.
