Muscles and joints are an important part of the musculoskeletal system. The structure of articulating surfaces and the type of connective tissues play a significant role in the range and plane of movement permitted at the joint. Skeletal muscles are responsible for movement and posture, and work best when used regularly to prevent atrophy.

Anatomical structures: The skull and cervical vertebrae of the neck move relative to the thoracic vertebrae and upper back. Reference axes: The movement is in the sagittal plane. The 'fulcrum' is not fixed due to the anatomy and movement of the cervical vertebrae, but it can loosely be positioned through the upper thoracic vertebrae.

Subsidence, settlement, heave, sway, bouncy floors, bulging walls, cracks, expansion and contraction are all forms of structural movement. Buildings and other built structures are moving all the time, but usually these movements are so small they are unnoticeable.

Identifying structural movement

All building structures experience movement and most buildings develop cracks in their fabric at some stage. Only rarely does cracking indicate serious structural failure. Many owners are unaware of a problem until their house goes through the selling process, when a valuation report for a lender recommends that an Engineer's report is obtained. This can be an unwelcome surprise for many vendors.

Why Building Structures experience movement | Arnold & Baldwin

Settlement is: the downward movement of the site on which the building stands, due to the application of the superimposed load (weight) from the building . Settlement Settlement problems normally exhibit themselves in the early life of the structure so older properties seldom suffer from on-going settlement

Yet the interplay of contending movements is understudied and undertheorized. This article begins to remedy this deficit by arguing that new work on political opportunity structure provides important insights and significant theoretical leverage for this study.

Anatomical terms of movement are used to describe the actions of muscles upon the skeleton. Muscles contract to produce movement at joints, and the subsequent movements can be precisely described using this terminology. The terms used assume that the body begins in the anatomical position. Most movements have an opposite movement – also known ...

A joint is the articulation, or junction, between two or more bones that acts as a pivot point for bony movement. Motion of the entire body or of a particular body segment generally occurs through the rotation of bones about individual joints.

Structure and Function of Joints | Musculoskeletal Key

Synovial joints allow the body a tremendous range of movements. Each movement at a synovial joint results from the contraction or relaxation of the muscles that are attached to the bones on either side of the articulation. The type of movement that can be produced at a synovial joint is determined by its structural type.

Pivot joints consist of the rounded end of one bone fitting into a ring formed by the other bone. This structure allows rotational movement, as the rounded bone moves around its own axis. An example of a pivot joint is the joint of the first and second vertebrae of the neck that allows the head to move back and forth.
